

Chapter 9

RESULTS AND DISCUSSION

The implementation of a water supply mobile application has resulted in considerable improvements in water management and user experience. Users may now effectively control their water consumption by measuring their usage, establishing consumption targets, and receiving personalised water saving recommendations through the application. This has raised user awareness of water use trends and empowered them to make informed decisions to reduce their water consumption, encouraging sustainable water management. Furthermore, the application has proven invaluable in providing users with fast and accurate information about the state of water supply. Users can stay informed and plan accordingly with real-time notifications on disruptions, outages, and maintenance schedules. This has considerably increased customer satisfaction and decreased the annoyance caused by unexpected water service interruptions.

Moreover, the water supply authorities have seen increased efficiency in water delivery as a result of the installation of this mobile application. The application's features have streamlined company operations, allowing them to respond to challenges quickly and effectively. This has resulted in speedier resolution of water supply problems, reduced downtime, and ensured that users have reliable water delivery. Overall, the water supply mobile app has proven to be an invaluable resource for both customers and water supply authorities. It has helped to improve water management practises, promote user participation in conservation efforts, and raise operational efficiency. In the future, continued development and refinement of the application will optimise water delivery services and encourage sustainable water resource management (Fig 9.1 - 9.4 shows the screenshots of the application).
